

On the Uniqueness of Best Simultaneous Approximations in Finite-Dimensional Subspaces

Natia Mshvidobadze

Department of Mathematics, King Saud University, Riyadh, Saudi Arabia

Abstract: This study explores the uniqueness of best simultaneous approximation of two continuous functions on a closed interval from a finite dimensional subspace. The uniqueness condition is demonstrated to imply that the subspace is Chebyshev. The research examines special case of even and odd function approximations, providing valuable insights into the approximation behavior from finite-dimensional spaces.

Keywords: Simultaneous Approximation, Chebyshev Subspace, Uniqueness, even functions, odd functions, Finite Dimensional Subspaces.

1. Introduction

Let $C[a, b]$ be the set of all real-valued continuous functions defined on the closed interval $[a, b]$ with the uniform norm $\| \cdot \|$.

For $f \in C[a, b]$,
 $\|f\| = \max \{ |f(x)|, x \in [a, b] \}$.

The norms $\|F\|_{A(\infty)}$ on $E = C[a, b] \times C[a, b]$ is defined as follows:

For $F = (F_1, F_2) \in E$
 $\|F\|_{A(\infty)} = \max \{ \|F_1\|, \|F_2\| \}$

Now if S is an n -dimensional subspace of $C[a, b]$, then $U = \{ (s, s) : s \in S \}$ forms an n -dimensional subspace of E and there exist $u^* = (s^*, s^*)$ and $v^* = (t^*, t^*)$ where $s^*, t^* \in S$ such that :

$$\begin{aligned} \|F - u^*\|_{A(\infty)} &= \inf_{u \in U} \|F - u\|_{A(\infty)} \\ &= \inf_{s \in S} \max \{ \|F_1 - s\|, \|F_2 - s\| \} \\ &= \|F_k - s^*\| \quad k = 1 \text{ or } 2. \end{aligned}$$

Such s^* is termed as the best $A(\infty)$ simultaneous approximation to $F = (F_1, F_2)$ from S . The set of all best $A(\infty)$ simultaneous approximations to F from S will be denoted by $P_S(F, \infty)$. And $P_S(F_k)$ is the set of all best uniform approximation to F_k from S , $k \in \{1, 2\}$.

We are interested in the uniqueness of the best $A(\infty)$ simultaneous approximation of two continuous functions from a finite dimensional subspace. In section two we will show that the uniqueness of the best $A(\infty)$ simultaneous approximation of two continuous functions from a finite dimensional subspace S implies that S is a Chebyshev subspace.

Definition 1: A point $t \in [a, b]$ is called a straddle point for two functions f and g in $C[a, b]$ if there exists $\sigma = \pm 1$ such that

$$\|f\| = \sigma f(t), \quad \|g\| = -\sigma g(t).$$

Definition 2: The functions f and $g \in C[a, b]$ are said to have d alternations on $[a, b]$ if there exists $d + 1$ distinct points $x_1 < \dots < x_{d+1}$ in $[a, b]$ such that for some $\sigma = \pm 1$,
 $f(x_i) = \sigma \|f\|$, if i is odd
 $g(x_i) = -\sigma \|g\|$, if i is even

or

$$\begin{aligned} g(x_i) &= \sigma \|g\|, \text{ if } i \text{ is odd} \\ f(x_i) &= -\sigma \|f\|, \text{ if } i \text{ is even.} \end{aligned}$$

Definition 3 Let S be the span of $\{u_1, u_2, \dots, u_n\}$ where $u_1, u_2, \dots, u_n$ are continuous functions on the closed interval $[a, b]$, we say that S is a Chebyshev subspace of $C[a, b]$ if

$$\begin{aligned} \det [u_i(x_j)]_{i,j=1}^n &\neq 0 \quad \text{for any set of points} \\ a \leq x_1 < x_2 < \dots < x_n \leq b. \end{aligned}$$

The notations in this section will be used throughout this paper. Theorems 1 of this section and the remark thereafter which are needed for our analysis, are direct consequences of theorems 1 and 3 of [2].

Theorem 1 Let S be an n -dimensional Haar subspace of $C[a, b]$, if $F_1 \geq F_2$ on $[a, b]$ then $s^* \in P_S(F, \infty)$ if and only if $F_1 - s^*$ & $F_2 - s^*$ have a straddle point or n alternations on $[a, b]$ with $\|F_1 - s^*\| = \|F_2 - s^*\|$. Furthermore, if $F_1 - s^*$ & $F_1 - s^*$ have n alternations on $[a, b]$ then s^* is unique.

Remark: If $t \in [a, b]$ is a straddle point for $F_1 - s^*$ & $F_2 - s^*$, $F_1 \geq F_2$ on $[a, b]$ then

$$\begin{aligned} (F_1 - F_2)(t) &= (F_1 - s^*)(t) + (F_2 - s^*)(t) \\ &= \|F_1 - s^*\| + \|F_2 - s^*\| \geq \|F_1 - F_2\|. \end{aligned}$$

This implies that $(F_1 - F_2)(t) = \|F_1 - F_2\|$ and $\|F_1 - s^*\| + \|F_2 - s^*\| = \|F_1 - F_2\| \leq \|F_1 - s\| + \|F_2 - s\| \quad \forall s \in S$.

2. The Main Result

Theorem 2 Let S be n -dimensional subspace of $C[a, b]$. If the best $A(\infty)$ simultaneous approximation to any two continuous functions on $[a, b]$ is unique, then S is a Chebyshev subspace.

Proof

Suppose that the conditions of the theorem are satisfied but S is not a Chebyshev subspace. If $S = \text{span} \{u_1, u_2, \dots, u_n\}$ where $u_1, u_2, \dots, u_n$ are continuous functions on the closed interval $[a, b]$, then there exists a set of points $a \leq x_1 < x_2 < \dots < x_n \leq b$ such that the matrix

$$\begin{bmatrix} u_1(x_1) & u_1(x_2) & \dots & u_1(x_n) \\ \vdots & \vdots & \ddots & \vdots \\ u_n(x_1) & u_n(x_2) & \dots & u_n(x_n) \end{bmatrix}$$

is singular.

We can select nonzero vectors $(a_1, a_2, \dots, a_n)$ and $(b_1, b_1, \dots, b_n)$ to be orthogonal to the columns and rows, respectively, of this matrix. Hence $\sum_{k=1}^n a_k u_k(x_i) = 0$ and $\sum_{k=1}^n b_k u_j(x_k) = 0$, $i, j = 1, \dots, n$. Taking $W = \sum_{k=1}^n a_k u_k$ then $W(x_i) = 0$, $i = 1, \dots, n$. And we may assume that $\|W\| < 1$. Select $\{F_1, F_2\} \subseteq C[a, b]$ such that $F_1 \geq F_2$ on $[a, b]$, $\|F_1\| = \|F_2\| = 1$ and $F_1(x_j) = \text{sgn } b_j$ if j is odd $F_2(x_j) = \text{sgn } b_j$ if j is even or $F_1(x_j) = \text{sgn } b_j$ if j is even $F_2(x_j) = \text{sgn } b_j$ if j is odd. So if $G_1(x) = F_1(x)[1 - |W(x)|]$ and $G_2(x) = F_2(x)[1 - |W(x)|]$, then $G_1(x_j) = F_1(x_j) = \text{sgn } b_j$ if j is odd and $G_2(x_j) = F_2(x_j) = \text{sgn } b_j$ if j is even or $G_1(x_j) = F_1(x_j) = \text{sgn } b_j$ if j is even and $G_2(x_j) = F_2(x_j) = \text{sgn } b_j$ if j is odd.

Now, if $\|G - u\|_{A(\infty)} < 1$ where $G = (G_1, G_2)$ and $u = (s, s)$ for some $s \in S$ then $\|G_1 - s\| < 1$ and $\|G_2 - s\| < 1$ which implies that $\text{sgn } s(x_j) = \text{sgn } b_j$, $j = 1, \dots, n$, contradicting the equation $\sum_{k=1}^n b_k(x_k) = 0$. Therefore $\|G - u\|_{A(\infty)} \geq 1$ for all $s \in S$.

For $0 \leq \lambda \leq 1$ we have

$$\begin{aligned} |G_1(x) - \lambda W(x)| &\leq |G_1(x)| + \lambda |W(x)| \\ &= |F_1(x)|[1 - |W(x)|] + \lambda |W(x)| \\ &\leq 1 - |W(x)| + \lambda |W(x)| \leq 1 \\ \text{and} \\ |G_2(x) - \lambda W(x)| &\leq |G_2(x)| + \lambda |W(x)| \\ &= |F_2(x)|[1 - |W(x)|] + \lambda |W(x)| \\ &\leq 1 - |W(x)| + \lambda |W(x)| \leq 1. \end{aligned}$$

Henceforth λW is a best $A(\infty)$ -simultaneous approximation to F_1 and F_2 where $0 \leq \lambda \leq 1$. That is best $A(\infty)$ -simultaneous approximation to G_1 and G_2 from S is not unique contradicting the assumption and the theorem is proved.

Now we consider different case, taking $S = \text{span}\{1, x, x^2, \dots, x^{n-1}\}$, $[a, b] = [-1, 1]$, $F_1 = x^m$, $F_2 = x^k$ and $F = (F_1, F_2)$ where n, m and k are integers with $k > m \geq n \geq 2$.

Lemma 1 If $s^* \in P_S(F, \infty)$, then $\|F_1 - s^*\| = \|F_2 - s^*\|$.

Proof

First we note that if m is an even integer then $F_1 \geq F_2$ on $[-1, 1]$ and from Lemma (1) of [2] we must have $\|F_1 - s^*\| = \|F_2 - s^*\|$.

If m is an odd integer then $F_1 \geq F_2$ on $[0, 1]$ and $F_2 \geq F_1$ on $[-1, 0]$.

Suppose $\|F_1 - s^*\| > \|F_2 - s^*\|$ then $s^* \in P_S(F_1)$ and there exists a point set

$X_1 = \{-1 \leq x_1 < x_2 < \dots < x_{n+1} \leq 1\}$ such that $F_1(x_i) - s^*(x_i) = \sigma (-1)^i \|F_1 - s^*\|$, $i = 1, \dots, n+1$, $\sigma = \pm 1$.

Since $n+1 > 2$ then there exists a point $y \in X_1 \cap [-1, 0]$ such that

$$\begin{aligned} \|F_1 - s^*\| &= F_1(y) - s^*(y) \leq F_2(y) - s^*(y) \leq \|F_2 - s^*\| \\ \text{or } t \in X_1 \cap [0, 1] \text{ such that} \\ \|F_1 - s^*\| &= -F_1(t) + s^*(t) \leq -F_2(t) + s^*(t) \leq \|F_2 - s^*\| \end{aligned}$$

and this contradict the assumption, hence we must have $\|F_1 - s^*\| = \|F_2 - s^*\|$.

Proceeding as above if $\|F_2 - s^*\| > \|F_1 - s^*\|$ completes the proof.

Lemma 2

If both m and k are odd integers and $s^* \in P_S(F, \infty)$ such that

$F_1 - s^*$ & $F_2 - s^*$ have n alternations on $[-1, 1]$, then s^* is odd function.

Proof

Select $s \in S$ such that $s(x) = -s^*(-x)$ for every $x \in [-1, 1]$, so for any $x \in [-1, 1]$ we have:

$$\begin{aligned} (F_j - s^*)(x) &= F_j(x) + s(-x) = -F_j(-x) + s(-x) \\ &= 1 \text{ or } 2. \end{aligned}$$

Which implies that $s \in P_S(F, \infty)$. But s^* is unique, so $s^* = s$ and this completes the proof.

Theorem 3

If both m and k are odd integers and $s^* \in P_S(F, \infty)$ such that $F_1 - s^*$ & $F_2 - s^*$ have n alternations on $[-1, 1]$, then $s^* \in P_S(F_j)$ $j = 1$ or 2 .

Proof

Let $X = \{-1 \leq x_1 < x_2 < \dots < x_{n+1} \leq 1\}$ be the alternating set, that is

$$(F_i - s^*)(x_i) = (-1)^{i+k} \|F_i - s^*\| \quad i = 1, \dots, n+1, \quad k = 0 \text{ or } 1.$$

$$F_i = \begin{cases} F_1 & \text{if } i \text{ is odd} \\ F_2 & \text{if } i \text{ is even} \end{cases}, \text{ or}$$

$$F_i = \begin{cases} F_2 & \text{if } i \text{ is odd} \\ F_1 & \text{if } i \text{ is even} \end{cases}$$

Now assume $k = 0$ and $F_i = \begin{cases} F_1 & \text{if } i \text{ is odd} \\ F_2 & \text{if } i \text{ is even} \end{cases}$,

then:

$(F_1 - s^*)(y_i) = -\|F_1 - s^*\| \quad i = 1, \dots, q$
 $(F_2 - s^*)(z_i) = \|F_2 - s^*\| \quad i = 1, \dots, r$,
 where $Y = \{y_1, y_2, \dots, y_q\}$, $Z = \{z_1, z_2, \dots, z_r\}$,
 $X = Y \cup Z$ and
 $n + 1 = q + r$. If $n + 1$ is even then $r = q$ and if $n + 1$ is odd then $r = q + 1$ or
 $q = r + 1$.

By lemma 3 s^* is odd function and we have:

$$\begin{aligned} (F_1 - s^*)(-y_i) &= \|F_1 - s^*\| \quad i = 1, \dots, q \\ (F_2 - s^*)(-z_i) &= -\|F_2 - s^*\| \quad i = 1, \dots, r \end{aligned}$$

From the characterization theorem of best uniform approximation, it follows that

$s^* \in P_s(F_j) \quad j = 1, 2$ if n is odd. And if n is even with $q = r + 1$ then

$s^* \in P_s(F_1)$ also $s^* \in P_s(F_2)$ if $r = q + 1$. The proof is the same for the other cases.
